# Homotopy type theory

#### Ingo Blechschmidt November 25th, 2014

### **Outline**

- 1 Foundations
  - What are foundations?
  - What's problematic with set-based foundations?
- 2 Basics on homotopy type theory (HoTT)
  - What is homotopy type theory?
  - What are values and types?
  - What is the dependent equality type?
- 3 Homotopy theory in HoTT
  - How are types like spaces?
  - How are constructions encoded?
  - What are higher inductive definitions?
  - What is circle induction?
- 4 Further topics
  - What is type truncation?
  - What is the univalence axiom?
  - What's the status of the axiom of choice?
  - What are models of HoTT?
  - What are applications?
- 5 References

### What are foundations?

- Foundations set the logical context for doing maths.
- Their details don't matter in everyday work (mostly).
- But their main concepts do.

http://collabcubed.com/2012/10/24/high-trestle-trail-bridge-rdg/

### What are foundations?

- Foundations set the logical context for doing maths.
- Their details don't matter in everyday work (mostly).
- But their main concepts do.
- Classical foundations are set-based (ZF, ZFC, ...): Everything is a set.
- $0 := \emptyset, \quad 1 := \{0\}, \quad 2 := \{0,1\}, \quad \dots$
- $(x,y) := \{ \{x\}, \{x,y\} \}$  (Kuratowski pairing)
- (x,y,z) := (x,(y,z))
- maps: (X, Y, R) with  $R \subseteq X \times Y$  such that ...

# What's wrong with set-based foundations?

Set-based foundations ...

- do not reflect typed mathematical practice,
- do not respect equivalence of structures,
- require complex encoding of "higher-level" subjects, complicating interactive proof environments.

## What is homotopy type theory?

- Homotopy type theory is a new foundational theory.
- Basic notions have a homotopy-theoretic flavour.
- One can start doing "real mathematics" right away, without complex encodings.
- Initiated by Voevodsky in 2005.

Some participants of the IAS special year

# What is homotopy type theory?

#### Homotopy type theory ...

- is elegant,
- reflects mathematical practice,
- contains wondrous new concepts,
- ensures that everything respects equivalences,
- simplifies the plumbing of homotopy theory,
- allows for accessible computer formalization.

## What are values and types?

- In type theory, there are **values** and **types**.
- Every value is of exactly one type.
- Types may depend on values.

 $7: \mathbb{N}$ 

 $(3,5): \mathbb{N} \times \mathbb{N}$ 

 $\mathsf{succ}: \mathbb{N} \to \mathbb{N}$ 

zero vector :  $\mathbb{R}^n$   $(n : \mathbb{N})$ 

## What are values and types?

- In type theory, there are **values** and **types**.
- Every value is of exactly one type.
- Types may depend on values.

$$7: \mathbb{N}$$
$$(3,5): \mathbb{N} \times \mathbb{N}$$
$$\mathsf{succ}: \mathbb{N} \to \mathbb{N}$$

zero vector :  $\mathbb{R}^n$   $(n : \mathbb{N})$ 

Let B(x) be a type family depending on x : A.

- $\blacksquare \prod_{x:A} B(x) = "\{f: A \to ?? | f(a): B(a) \text{ for all } a: A\}"$

# What is the dependent equality type?

In set theory, for a set X and elements  $x, y \in X$ :

- "x = y" is a proposition.
- Set theory is **layered above** predicate logic.

In type theory, for a type X and values x, y : X:

- There is the **equality type**  $Id_X(x,y)$  or  $(x =_X y)$ .
- To verify that "x = y", exhibit a value of (x = y).
- Have  $refl_x : (x = x)$ .
- Identity types may contain zero or many values!

Intuition: (x = y) is the type of **proofs** that "x = y".

# What is the dependent equality type?

In set theory, for a set *X* and elements  $x, y \in X$ :

- "x = y" is a proposition.
- Set theory is **layered above** predicate logic.

In type theory, for a type X and values x, y : X:

- There is the **equality type**  $Id_X(x,y)$  or  $(x =_X y)$ .
- To verify that "x = y", exhibit a value of (x = y).
- Have  $refl_x : (x = x)$ .
- Identity types may contain zero or many values!

Intuition: (x = y) is the type of **proofs** that "x = y".

Intuition: (x = y) is the type of paths  $x \rightsquigarrow y$ .

## How are types like spaces?

homotopy theory	type theory
space $X$ point $x \in X$ path $x \rightsquigarrow y$ (continuous) map	type $X$ value $x : X$ value of $(x = y)$ value of $X \to Y$

■ A **homotopy** between maps  $f, g : X \to Y$  is a value of

$$(f \simeq g) :\equiv \prod_{x \in X} (f(x) = g(x)).$$

■ A space *X* is **contractible** iff

$$\mathsf{IsContr}(X) :\equiv \sum_{x:X} \prod_{y:X} (x = y).$$

## How are types like spaces?

■ "The type *X* is **contractible**":

$$\mathsf{IsContr}(X) :\equiv \sum_{x:X} \prod_{y:X} (x = y).$$

■ "The type *X* is a **mere proposition**":

$$\mathsf{IsMereProp}(X) :\equiv \prod_{x,y:X} (x = y)$$

■ "The type *X* is a **set** or **discrete space**":

$$\mathsf{IsSet}(X) :\equiv \prod_{x,y:X} \mathsf{IsMereProp}(x = y)$$

■ For instance, N is a set.

## How are types like spaces?

■ Functions are automatically **continuous/functorial**:

$$(x = y) \longrightarrow (f(x) = f(y)).$$

■ Type families  $P: X \to \mathcal{U}$  automatically behave like **fibrations**, in that fibers over connected points are equivalent:

$$(x = y) \longrightarrow (P(x) \simeq P(y)).$$

### How are constructions encoded?

■ The **fiber** of a map  $f: X \to Y$  over a point y: Y is

$$\operatorname{fib}_f(y) :\equiv \sum_{x \in X} (f(x) = y).$$

 $\blacksquare$  The path space of X is

$$X^I := \sum_{x,y:X} (x = y).$$

 $\blacksquare$  The **based loop space** of *X* at *x* is

$$\Omega^1(X, x) :\equiv (x = x).$$

■ The path fibration of (X, x) is the map

$$\mathsf{fst}: \sum_{y:X} (x=y) \to X.$$

### How are constructions encoded?

■ The **fiber** of a map  $f: X \to Y$  over a point y: Y is

$$\operatorname{fib}_f(y) :\equiv \sum_{x:X} (f(x) = y).$$

 $\blacksquare$  The path space of X is

$$X^I :\equiv \sum_{x,y:X} (x = y).$$

■ The **based loop space** of X at x is

$$\Omega^1(X, x) :\equiv (x = x).$$

■ The **path fibration** of (X, x) is the map

$$\mathsf{fst}: \sum_{y:X} (x=y) \to X.$$

## What are higher inductive definitions?

The type  $\mathbb{N}$  of natural numbers is **freely generated** by

- $\blacksquare$  a point  $0: \mathbb{N}$  and
- $\blacksquare$  a function succ :  $\mathbb{N} \to \mathbb{N}$ .

This definition gives rise to an induction principle

$$\prod_{A:\mathbb{N}\to\mathcal{U}} \Bigl(A(0)\times\Bigl(\prod_{n:\mathbb{N}} A(n)\to A(\mathrm{succ}(n))\Bigr) \longrightarrow \prod_{n:\mathbb{N}} A(n)\Bigr),$$

and a recursion principle

$$\prod_{X:\mathcal{U}} \Big( X \times \Big( \mathbb{N} \to (X \to X) \Big) \longrightarrow (\mathbb{N} \to X) \Big).$$

# How to present famous spaces?

### The **circle** $S^1$ is generated by

- $\blacksquare$  a point base :  $S^1$  and
- $\blacksquare$  a path loop : (base = base).

### The **sphere** $S^2$ is generated by

- $\blacksquare$  a point base :  $S^2$  and
- $\blacksquare$  a path surf : (refl<sub>base</sub> = refl<sub>base</sub>).

### The **torus** $T^2$ is generated by

- $\blacksquare$  a point  $b: T^2$ ,
- a path p : (b = b),
- $\blacksquare$  a path q:(b=b), and
- a 2-path t : (p q = q p).

# How to present famous spaces?

#### The **suspension** $\Sigma X$ of X is generated by

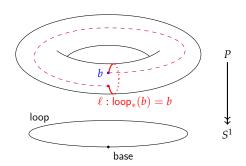

- a point  $N : \Sigma X$  and
- $\blacksquare$  a point  $S : \Sigma X$  and
- a function merid :  $X \rightarrow (N = S)$ .

### The **cylinder** Cyl(X) of X is generated by

- a function bot :  $X \to \text{Cyl}(X)$  and
- a function top :  $X \to \text{Cyl}(X)$  and
- a function seg :  $\prod_{x:X} (bot(x) = top(x))$ .

Of course, we can show  $Cyl(X) \simeq X \times I \simeq X$ .

### What is circle induction?

The **induction principle** of  $S^1$  states: Given  $P: S^1 \to \mathcal{U}$ ,

■ a point  $b : P(\mathsf{base})$ , and ■ a path  $\ell : \mathsf{loop}_*(b) = b$ 

there is a function  $f: \prod_{x:S^1} P(x)$  such that

$$f(base) \equiv b$$
 and

$$f(loop) = \ell.$$

## What is type truncation?

Let *X* be a type.

The **propositional truncation**  $||X||_{-1}$  is generated by

- $\blacksquare$  a function  $X \to ||X||_{-1}$  and
- for any  $x, y : ||X||_{-1}$ , a path x = y.

The **0-truncation**  $||X||_0$  is generated by

- a function  $X \rightarrow ||X||_0$  and
- for any  $x, y : ||X||_0$ , p, q : (x = y), a path p = q.

The **fundamental group** of  $(X, x_0)$  is

$$\pi_1(X, x_0) := \|\Omega^1(X, x_0)\|_0 := \|(x_0 = x_0)\|_0.$$

### What is the univalence axiom?

An **equivalence** is a function  $f: X \to Y$  such that

$$\mathsf{IsEquiv}(f) :\equiv \prod_{y:Y} \mathsf{IsContr}(\mathsf{fib}_f(y)).$$

Types *X* and *Y* are **equivalent** iff

$$(X \simeq Y) := \sum_{f:X \to Y} \mathsf{lsEquiv}(f).$$

The univalence axiom states: The canonical function

$$(X = Y) \longrightarrow (X \simeq Y)$$

is an equivalence, for all types X and Y.

### What's the status of the axiom of choice?

■ The following proposition is **just true**, but is not a faithful rendition of the axiom of choice:

$$\left(\prod_{x:A}\sum_{y:B}R(x,y)\right)\longrightarrow\sum_{f:A\to B}\prod_{x:A}R(x,f(x)).$$

■ The real axiom of choice,

$$\left(\prod_{x:A}\left\|\sum_{y:B}R(x,y)\right\|_{-1}\right)\longrightarrow\left\|\sum_{f:A\to B}\prod_{x:A}R(x,f(x))\right\|_{-1},$$

can be added as an axiom, but is rarely needed.

### What's the status of the axiom of choice?

■ The following proposition is **just true**, but is not a faithful rendition of the axiom of choice:

$$\left(\prod_{x:A}\sum_{y:B}R(x,y)\right)\longrightarrow\sum_{f:A\to B}\prod_{x:A}R(x,f(x)).$$

■ The real axiom of choice,

$$\left(\prod_{x:A}\left\|\sum_{y:B}R(x,y)\right\|_{-1}\right)\longrightarrow\left\|\sum_{f:A\to B}\prod_{x:A}R(x,f(x))\right\|_{-1},$$

can be added as an axiom, but is rarely needed.

■ The law of excluded middle is too rarely needed.

$$\mathsf{LEM} :\equiv \prod_{A:\mathcal{U}} \Big( \mathsf{IsMereProp}(A) \to A + \neg A \Big).$$

### What are models of HoTT?

Conjecturally, HoTT can be interpreted in any  $(\infty, 1)$ -topos. Verified models include

- ∞Grpd, i. e. a model in simplicial sets, and
- $(\infty, 1)$ -presheaf toposes over elegant Reedy categories.

Thus, any theorem proven in HoTT holds in the context of classical homotopy theory and in more general contexts.

## What are applications?

Homotopy type theory **subsumes all of classical mathematics**, by using the fragment of discrete types.

The following subjects have received special treatment:

- Homotopy theory (duh)
- Category theory
- Data type theory
- Your subject here!

Also, HoTT can be used as the **internal language** of  $(\infty, 1)$ -toposes.

# What is homotopy type theory?

#### Homotopy type theory ...

- is elegant,
- reflects mathematical practice,
- contains wondrous new concepts,
- ensures that everything respects equivalences,
- simplifies the plumbing of homotopy theory,
- allows for accessible computer formalization.
